Intraoperative equipment failures are increasingly rare events, but may cause serious harm based on an analysis of the American Society of Anesthesiologists (ASA) Closed Claims database. Pre-anesthesia checkout procedures strive to make these events preventable, but certain failures cannot be prevented with a standard checklist. A task force organized under the ASA Committee on Equipment and Facilities initiated a comprehensive anesthesia apparatus checkout recommendation which we follow at our institution. Despite this practice, our institution recently experienced two critical malfunctions of the General Electric Aisys Anesthesia Carestation (GE Healthcare, Chicago, IL).

Both instances resulted in power loss to the anesthesia monitor display unit leading to the loss of all ventilation parameters, cessation of mechanical ventilation, and the inability to use volatile anesthetics. During both cases, the cause of the anesthesia machine malfunction was not immediately known, but both intraoperative teams eventually identified a loose connection behind the anesthesia monitor display unit (Figure 1). One case identified a missing securing screw where the System Power Interface cable (Cable A) is connected to the display unit. For the second case, the cables appeared connected, but an untightened screw was discovered upon closer examination. After firmly reinserting the Cable A into the back of the monitor, the anesthesia machine progressed through the startup cycle. The anesthesia monitor display unit then displayed a nonspecific error screen (“internal problem prevents normal operation”) and instructed the user to manually ventilate with the alternate O₂ control and cycle power on the anesthesia machine (Figure 2). The anesthesia machine progressed through the startup cycle until the communication cable between the anesthesia controller board and the anesthesia monitor display unit was reestablished firmly. A similar error has also occurred with cable “C” disconnections (Figure 1), which interrupt anesthesia machine external communication to the electronic health record.

Upon review of the error history after the events, the logs noted two errors: “DU to PSC Comm Error” and “POWER CNTRL COM FAIL,” pointing to a disconnection of the communication cable behind the anesthesia monitor display unit (Figure 3). Recreating this error with a biomedical technician demonstrated that even a slightly untightened screw can lead to a transient cable disconnection with movement of the monitor arm. The machine will not initiate the startup sequence until the communication cable is reestablished firmly. A similar error has also occurred with cable “C” disconnections (Figure 1), which interrupt anesthesia machine external communication to the electronic health record.

Our anesthesia machines are fifteen years old and nearing fleet replacement. On the 12-month preventative maintenance (PM) schedule, checking these communication cables is listed under “Visual Inspection Procedure.” These loose connections are also not detected by the automated machine check or standard preinduction checklists. These cases are the first occurrences of this malfunction at our institution, but we are concerned that this will happen with increasing frequency with other anesthesia machines in our fleet as the screws continue to disengage over time.

A solution to this fault would be placement of a retention clip as a redundant securement mechanism. Redundancy to prevent failure of critical systems is a hallmark of safety innovation not only in anesthesia, but also in aviation and other industries. Improved designs can prevent errors particularly for rare problems where standard checklists may fail. Unfortunately, this proposal may not be implemented.

GE HealthCare Response: Recurrent Intraoperative Anesthesia Machine Malfunctions

Dear APSF Rapid Response,

GE HealthCare would like to thank the team from University of California San Francisco School of Medicine for submitting their experience with an Aisys Anesthesia Machine display cable disconnection resulting in loss of the display and control during two procedures. In response to this report, GE HealthCare performed an extensive review of the technical description of the failure, the design of the display cable, and GE HealthCare’s servicing documentation (Technical Reference Manual).

Per the description in the report, the cable that became disconnected is the communication cable between the Display Unit and the Anesthesia Control Board. When there is a communication loss between the Display Unit CPU and the Anesthesia Control Board CPU, the system is designed to display the “System Malfunction” screen as described in the report.

The report points out that the loose cable connection is not detected by the pre-use machine checkout and/or during preventative maintenance. As this condition is a result of a communication loss between the Display Unit CPU and the Anesthesia Control Board CPU, the machine will enter the System Malfunction state if the communication loss is greater than 10 seconds regardless of the state of the machine (Power-up, Checkout, or Planned Maintenance). Therefore, if the disconnect were to have occurred, or been present, during pre-use machine checkout it would have been identified.

The Maintenance Procedures section in the Technical Reference Manual recommends a visual inspection procedure of the machine including a step to “Check all external electrical cabling. Ensure all are correctly connected and are not deteriorated.” This portion of the Maintenance Procedure is intended for the service personnel to check the condition and tightness of the external cables, including the display communication cable.

Also, the recommended maintenance for the Aisys Anesthesia Machine, as detailed in the Maintenance Procedures section, requires the 3v battery in the display CPU to be replaced every 48-months. The replacement of this battery requires the display cables to be disconnected and the display to be removed from the Aisys Anesthesia Machine. Therefore, it is likely based on the age of the machines that these display cables have been removed and reinstalled at least three times since the machine was manufactured.

GE HealthCare strives for continuous improvement and will consider the authors’ suggestions for maintenance improvements and cable retention for future designs.

Sincerely,
Anthony Bean
